MATH 2300 – MULTIVARIABLE CALCULUS

Examples of section 12.5

Question 1. Does the given line and plan intersect? Where?

$$x = 1 - t$$
, $y = 1 + 2t$, $z = 3 - t$ and $3x - y + 2z = 5$.

Solution 1. Plugging x = 1 - t, y = 1 + 2t, and z = 3 - t into the equation of the plane yields

$$3(1-t) - (1+2t) + 2(3-t) = 5 \Rightarrow t = -3.$$

Using t = -3 into the parametric equations of the line we find (-4, -5, 6).

Question 2. Find the point of intersection of the lines

$$x-2-t=0, y-3+2t=0, z-1+3t=0,$$

$$x-3-t=0, y+4-3t=0, z-2+7t=0.$$

Solution 2. To find the intersection, we set the coordinates of the two lines equal to each other. Denoting by s the parameter on the second line, we find

$$2+t=3+s$$
, $3-2t=-4+3s$, $1-3t=2-7s$.

All three equations must be satisfied for an intersection to exist. Solving the first two equations gives t = 2 and s = 1. We verify that these values also satisfy the third equation. Using t = 2 on the first line (or s = 1 on the second line) produces (4, -1, -5).

Remark 1. In problem 2, a common mistake is not to relabel the parameter in the second line and write

$$2+t=3+t$$
, $3-2t=-4+3t$, $1-3t=2-7t$.

This is wrong since "t" is a placeholder for different parameters in the two equations.

Remark 2. In problem 2, a common mistake is to forget to verify that the third equation is satisfied. I.e., if we solve the first two equations and find t and s, it is still possible that the values found do not satisfy the third equation, in which case the lines do not intersect.
